

Recursive Algorithm for Backtracking-General Method

```
1  Algorithm Backtrack( $k$ )
2  // This schema describes the backtracking process using
3  // recursion. On entering, the first  $k - 1$  values
4  //  $x[1], x[2], \dots, x[k - 1]$  of the solution vector
5  //  $x[1 : n]$  have been assigned.  $x[ ]$  and  $n$  are global.
6  {
7      for (each  $x[k] \in T(x[1], \dots, x[k - 1])$ ) do
8      {
9          if ( $B_k(x[1], x[2], \dots, x[k]) \neq 0$ ) then
10         {
11             if ( $x[1], x[2], \dots, x[k]$  is a path to an answer node)
12                 then write ( $x[1 : k]$ );
13             if ( $k < n$ ) then Backtrack( $k + 1$ );
14         }
15     }
16 }
```

State Space Tree for 4-queens problem

N-Queens Problem

- **Condition to ensure - No two queens on same Row:**
 - Each queen must be on a different row ,hence queen i is to be placed on row i . Therefore all solutions to the n -queens problem can be represented as n -tuples (x_1, x_2, \dots, x_n) , where x_i is the column on which queen i is placed.
- **Condition to ensure - No two queens on same Column:**
 - Select a distinct value for each x_i
- **Condition to ensure - No two queens on same Diagonal**

				(i,j)	(k,l) are diagonal
				(2,3)	(1,2), (3,4)
					(1,4), (3,2), (4,1)
				(1,2)	(2,3), (3,4)
					(2,1)

N-Queens Problem

- If two queens are placed at positions (i, j) and (k, l). They are on the same diagonal then following conditions hold good.
 - 1) Every element on the **same diagonal that runs from the upper left to the lower right** has the same (row – column) value.

$$i - j = k - l \text{ -----(1)}$$

- 2) Similarly, every element on the **same diagonal that goes from the upper right to the lower left** has the same row + column value.

$$i + j = k + l \text{ -----(2)}$$

- First equation implies $j - l = i - k$
Second equation implies $j - l = k - i$
- Therefore, two queens lie on the same diagonal if and only if

$$|j - l| = |i - k|$$

Algorithm for N-Queens Problem

```
1  Algorithm NQueens( $k, n$ )
2  // Using backtracking, this procedure prints all
3  // possible placements of  $n$  queens on an  $n \times n$ 
4  // chessboard so that they are nonattacking.
5  {
6      for  $i := 1$  to  $n$  do
7      {
8          if Place( $k, i$ ) then
9          {
10              $x[k] := i$ ;
11             if ( $k = n$ ) then write ( $x[1 : n]$ );
12             else NQueens( $k + 1, n$ );
13         }
14     }
15 }
```

Algorithm for N-Queens Problem

```
1  Algorithm Place( $k, i$ )
2  // Returns true if a queen can be placed in  $k$ th row and
3  //  $i$ th column. Otherwise it returns false.  $x[ ]$  is a
4  // global array whose first  $(k - 1)$  values have been set.
5  // Abs( $r$ ) returns the absolute value of  $r$ .
6  {
7      for  $j := 1$  to  $k - 1$  do
8          if  $((x[j] = i) // \text{Two in the same column} |$ 
9              or  $(\text{Abs}(x[j] - i) = \text{Abs}(j - k)))$ 
10             // or in the same diagonal
11             then return false;
12      return true;
13  }
```
